SmartFileName.vi
Creates unique filenames based on a preferred file path.

preferred path [2] ~~~~~~~~ SMART NAMER ~~~~~~~~ [0] Smart Path
Allow Replacement (False) [1] ·············

[TF] If **Allow Replacement** is False and the   path already exists, the filename will be appended with a parenthetical number until a filename that does not already exist is found. If **Allow Replacement** is True, this VI outputs **path**.

[▸] **preferred path** specifies the preferred path of the file to be created. If this path is available, the output of **Smart Path** will be identical to this input. If the name is already taken, the behavior of **Smart Path** will depend on **Allow Replacement**.

[▸] **Smart Path** is the resulting path. If **Allow Replacement** is False, smart path will always be a unique location.
